

## Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact [support@jstor.org](mailto:support@jstor.org).

the dorsal column; the minor ascending root for these two nerves is found in the dorsal cornua. The acusticus has a three-fold origin, (1) general nuclear mass at that level; (2) from large cells which are the representative of the nucleus of Deiters; (3) from a round nucleus in the dorsal part of the gray matter. The large cells stand in connection with the roots of the acusticus on the one hand, the root fibres being large, and on the other appear to connect with the largest fibres in the cord, these latter running in the ventral columns and entering the ventral nerve roots. This is supposed to represent part of the mechanism for the equilibrium centre. Fibres lying in much the same position as Mauthner's fibres in the fish are found and homologized with the posterior longitudinal bundle. There are no uninterrupted tracts to the fore-brain, and there is nothing corresponding to a pyramidal tract. There is a well developed ventral commissure, an inferior olive, and the system of fibres in the fore-brain is complicated, but the individual fibres are not brought out by haematoxylin. K. confirms the existence of a corpus callosum. The olfactory nerves start from masses of fibres in the glomeruli, there being no cells in these glomeruli, and the olfactory nerves are partially crossed.

*Ueber die hinteren Nervenwurzeln, ihre Endigung in der grauen Substanz des Rückenmarkes und ihre centrale Fortsetzung im Letzteren.*  
BECHTEREW. His. und Braune's Archiv, 1887, No. 2 u. 3, S. 126.

The author investigated the foetal cord in man. He distinguishes two groups of fibres entering by the posterior nerve roots: one, early medullated (about the fifth month) with fibres of large caliber and lying mesial, the other becoming medullated later, with fibres of small size and lying lateral. The former appear on entering the cord to run mainly to the ventral portion of the column of Burdach, the latter goes chiefly to the most posterior part of the lateral column, the marginal zone (Randzone) of Lissauer. Both groups send small portions directly into the gelatinous substance. After a longer or shorter course all the fibres of the posterior roots enter the gray matter. There are no root fibres which pass directly to the oblongata. The following is the central course of the two components of the posterior nerve roots. The fibres of the mesial bundle pass in several directions after entering the gray matter; one part goes to the column of Clarke, another to the anterior cornu of the same side, to there unite with the cells; and a third to the anterior cornu of the other side, passing through the anterior commissure. The fibres of the lateral bundle pass cephalad for a distance in the marginal zone, then end into the small cells in the posterior cornu. From the column of Clarke there pass out fibres to the direct lateral cerebellar tract, others to the ventral portion of the column of Burdach and in part to the column of Goll, and finally bundles to the anterior cornu of the same side, and through the anterior commissure to the anterior cornu of the opposite side. From the small cells in the posterior cornu pass fibres to the limiting layer (Grenzschicht) and to the column of Goll. In the foetal cord the posterior commissure does not contain any medullated fibres. From these anatomical observations the author draws several physiological inferences which are here passed over.
